NANOCRYSTALLINE VITROPERM

ADVANCED MAGNETIC SOLUTIONS

VACUUMSCHMELZE

THE COMPANY VACUUMSCHMELZE

ADVANCED MAGNETIC SOLUTIONS

VAC is a leading manufacturer of magnetic materials and solutions. We passionately advance the technologies of today and tomorrow. As a reliable partner, we work with our customers to develop application solutions that make it possible to meet constantly increasing requirements. We push technical boundaries with groundbreaking solutions. The use of our materials as well as our refined solutions and their special magnetic properties are the key to making our customers' systems smaller, lighter, more efficient and, last but not least, safer. Thereby we contribute significantly to the saving of resources and the protection of our environment.

EMC PRODUCTS
BASED ON
NANOCRYSTALLINE VITROPERM

Nowadays power electronics have a decisive influence on the technology of electrical energy generation, distribution and conversion. Modern semiconductors enable electrical energy to be controlled and converted rapidly and safely with low losses. However, using today's fast switching technologies results in significant network disturbances. To minimize these disturbances and stabilizing electric networks, EMI filters according to latest international standards must be used. VAC's VITROPERM® EMC products make a significant contribution in building innovative and compact filter designs with lowest losses.

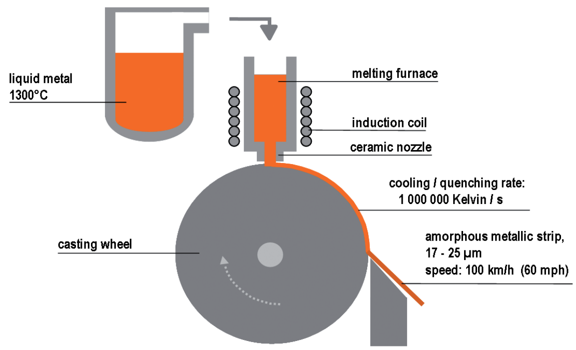
Our EMC products are used in a wide range of applications:

- **Switched-mode power supplies (SMPS)**
- **Solar inverters**
- **Frequency converters**
- **EMC filters**
- **Welding equipment**
- **Wind generators**
- **Induction hobs**
- **Automotive applications**
- **Uninterruptible power supplies (UPS)**

VITROPERM –
EXTENDING THE POSSIBILITIES OF IRON

Nanocrystalline VITROPERM alloys are based on Fe with Si and B with further additions of Nb and Cu. VAC pioneered the development of rapid solidification technology resulting in the production of thin tapes or ribbons approximately 20 µm thick. Special slitting and core winding machines produce tape-wound cores with external diameters ranging from 2 mm to 600 mm. A subsequent heat treatment at around 500 - 600 °C transforms the initially amorphous microstructure of the tape into the desired nanocrystalline state, this being a two-phase structure with fine crystalline grains (average grain diameter of 10 - 40 nm) embedded in an amorphous residual phase.

VITROPERM nanocrystalline alloys are optimized to combine highest permeability and lowest coercive field strength. The combination of very thin tapes and the relatively high electrical resistance (1.1 - 1.2 µΩm) ensures minimal eddy current losses and an outstanding frequency vs. permeability behaviour. Combined with a saturation flux density of 1.2 T and wide operational temperature range, these features combine to make VITROPERM a universal solution for most common EMC problems and vastly superior in many aspects to commonly used ferrite and amorphous iron materials.



with an amorphous structure (metallic glass).

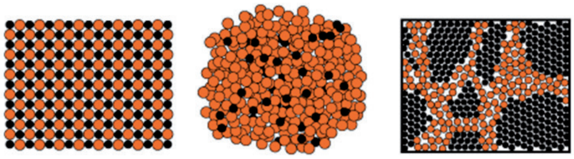


Fig 2: Crystalline structure, amorphous structure, nanocrystalline microstructure

SUPERIOR EMC FILTER AND COMMON MODE CHOKE DESIGN

Nanocrystalline cores are widely used in common mode choke (CMC) applications due to their unique combination of properties. By utilising low-cost raw materials (Fe-based) and modern, large-scale production, VITROPERM is a very competitive solution for a wide range of applications.

Our CMCs feature high attenuation which is maintained across a wide frequency range offering extremely broadband attenuation. In many cases, this characteristic can allow a reduction of the number of filter stages in multistage EMC filter configurations to reduce complexity, cost and filter volume. Ohmic (copper) losses are also reduced increasing the efficiency and lowering component temperature.

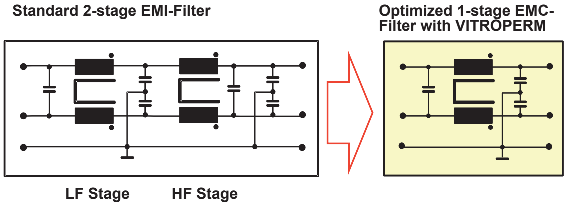

Fig. 3: Nanocrystalline chokes allow a reduction of filter stages

VACUUMSCHMELZE has extensive practical and theoretical expertise in the design of CMCs and filter configuration using nanocrystalline cores and components. At higher frequencies, the winding configuration has a major effect on the parameters of winding capacitance and leakage inductance and is therefore carefully considered in our choke designs. Figure 4 shows a comparison of insertion loss for two chokes which differ only in their winding configuration (core material, number of turns and wire thickness are identical in both cases). This illustrates how our design expertise can improve filter efficiency, maximize reliability and reduce costs.

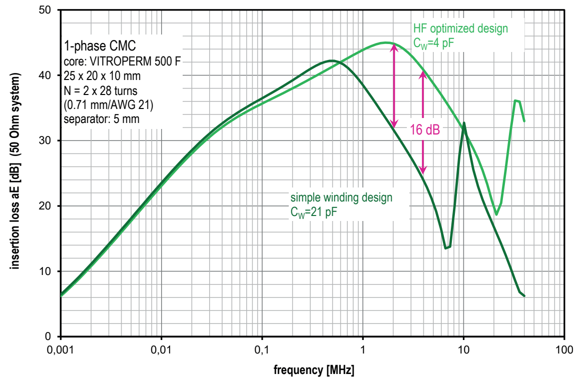

Fig. 4: Optimized choke design: improved attenuation of up to 16 dB (or more) at 4 MHz

FEATURES & BENEFITS OF VITROPERM NANOCRYSTALLINE CHOKES

ADVANTAGES	PRECONDITIONS / RELEVANT PROPERTIES
Small size	High μ, high B_S
Suitable for high currents and/or high voltages	High μ, high B_S, suitable core geometries
Single stage filter designs possible	Excellent broadband attenuation behaviour, high permeability, low-capacitance design, moderate reduction of μ up to high frequencies, low Q factor in 150 kHz range
High efficiency, low power loss	Low number of turns required for high L, reduction of filter stages
‘Green’, environmentally friendly	Low power loss, reduced use of material
Suitable for high and low ambient temperatures and high operating temperatures	High Curie temperature, material properties (μ, B_S, $_s$) nearly independent of temperature
‘Easy filter design’	Material properties (μ, B_S, $_s$) nearly independent of temperature, linear magnetization curve delivers stable impedance across a broad range of common mode currents – VAC choke design software available
UL-compliant designs	Suitable plastic materials meet UL1446 insulation requirements
Optimized solutions for a variety of different applications	A range of μ levels and VITROPERM alloys available
No operating noise	Material is practically magnetostriction-free
Best suited for winding of thick wires	Material is practically magnetostriction-free, coatings/casings are resistant against mechanical stress

VITROPERM VS. FERRITE

Due to the optimized high-frequency properties, the insertion loss of our nanocrystalline common mode chokes is superior compared to that of a typical ferrite choke in the relevant frequency range.

The properties of VITROPERM are very much different from conventional ferrites. In low-frequency ranges the permeability of VITROPERM 500 F is higher than that of ferrites. Nanocrystalline materials show a less marked reduction of permeability μ at higher frequencies. This has to be considered in the filter design for optimum solutions. The main physical and magnetic characteristics are illustrated in the following diagrams.

The permeability μ of VITROPERM 500 F is significantly higher than the μ of ferrites in the low frequency range. At higher frequencies the μ of both nanocrystalline materials remains above that of ferrites. A high choke impedance is preferred for a high attenuation. To achieve high impedance, high permeability core material rather than an increased number of turns must be used, as a low number of turns leads to low winding capacity and thus superior HF properties. VAC has focused on the favourable material properties of nanocrystalline cores to build an extensive practical and theoretical experience in the design of common-mode-chokes and filters. VAC's optimized chokes offer clearly improved HF-properties.

INSERTION LOSS

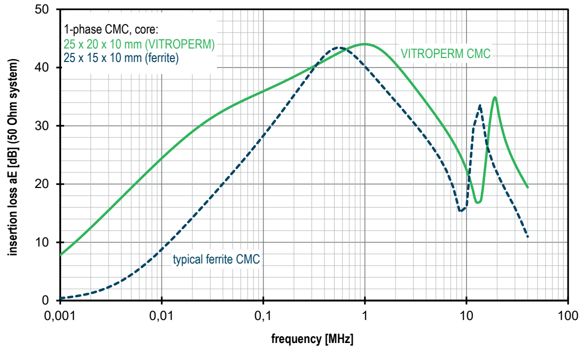

Fig. 5: Comparison of insertion loss of VITROPERM and ferrite

PERMEABILITY

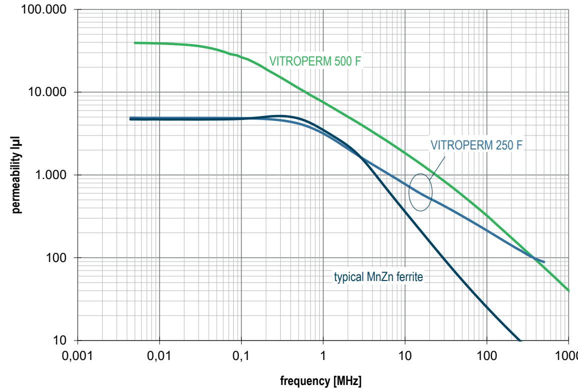

Fig. 6: Frequency response of the permeability of VITROPERM 500 F (μ = 40,000) and VITROPERM 250 F (μ = 5,000) in comparison to a typical MnZn ferrite (μ = 5,000)

PERMEABILITY AND MAGNETIZATION CURVE

As properties like the frequency dependence of permeability (fig. 7), μ(f) of VITROPERM 500 F and ferrites differ fundamentally, varied filter designs must be considered for optimization, the permeability of ferrites (μ = 5,000) shows a flat and linear characteristic up to approximately 1 MHz (ferrites with μ = 10,000 range up to approximately 200 kHz). In this flat range, the attenuation properties are determined by μ' and the impedance IZI is dominated by the inductance L. If the self-resonance of the choke is within this frequency range, the attenuation curve is narrowband and attenuation is primarily caused by reflection of the interference signal. The attenuation of ferrites is determined by its resistive parameters at frequencies above the frequency where the flat range of the curve ends, because the real part of the impedance Re(Z) accounts for the major share of the attenuation and the imaginary part of the complex permeability μ'' becomes the dominant factor. If the self-resonance of the choke is in this frequency range the attenuation characteristic becomes increasingly broadband.

VITROPERM is basically similar in this respect. The flat sector of μ(f) of VITROPERM 500 F ranges (depending on the initial permeability level) to frequencies of several 10 kHz (20 kHz in this example), only. Consequently, attenuation (or IZI) is already dominated by Re(Z) and is always broadband in the whole EMC-relevant range above 150 kHz. Inductance plays a minor role and describes the attenuation only partially. The determining factor is the total impedance. The approximation IZI =   L is valid for ferrite chokes. For VITROPERM chokes IZI >>   L applies. Attenuation primarily does not result from a reflection of the interference signal, but from its absorption.

Only if the different characteristics are considered, the design of optimized, compact and low-cost nanocrystalline chokes is possible. However, VITROPERM 250 F is an exception, because the flat μ(f) sector range is similar to μ = 5,000 ferrites to frequencies of up to 1 MHz and the attenuation is primarily inductive (fig. 8 a and b).

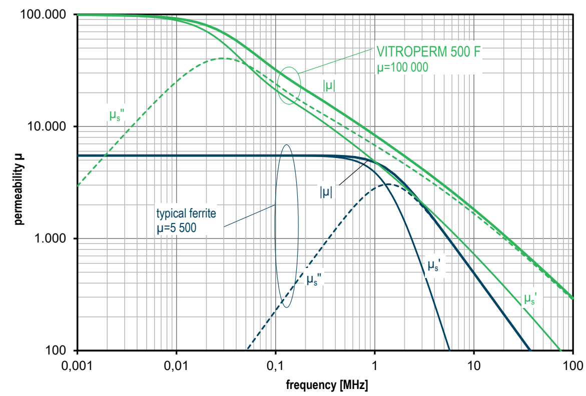

Fig. 7: Differences in the balance between μ' and μ'' for VITROPERM and ferrite lead to different attenuation mechanisms

MAGNETIZATION CURVE

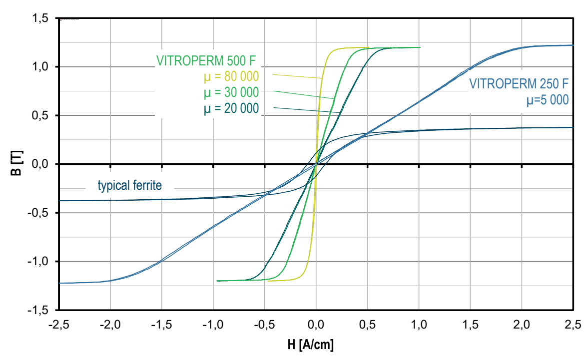

Fig. 8a: Hysteresis loops for various types of VITROPERM and typical MnZn ferrite

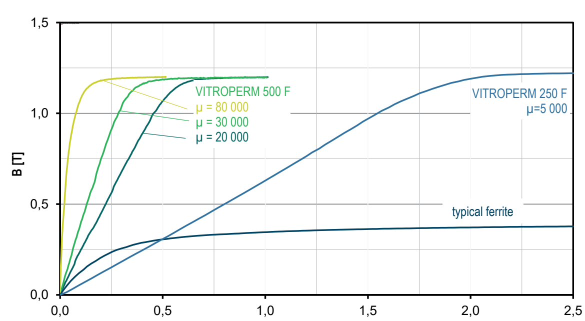

Fig. 8b: Magnetization curve of VITROPERM 500 F and VITROPERM 250 F in comparison to typical MnZn ferrite, showing noticeable differences in permeability (slope of the curve) and saturation flux density (B_S)

THERMAL PROPERTIES

The saturation flux density of VITROPERM changes by only a few percent in the operating temperature range of up to 150 °C, while MnZn ferrites decline by up to 40 % at temperatures above 100 °C (fig. 9). The high Curie temperature of VITROPERM alloys (above 600 °C), allows short term maximum operating temperatures as high as 180-200 °C[1)].

The permeability of VITROPERM typically changes by less than 10 % in the temperature range from -40 °C to 120 °C, while the permeability of MnZn ferrites can drift in a range of ± 40 - 60 % around the room temperature value (fig. 10).

THERMAL BEHAVIOUR

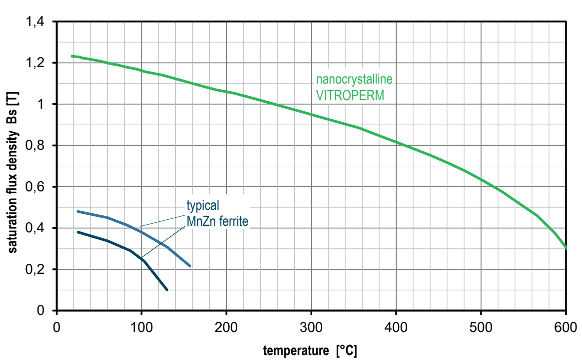

Fig. 9: Temperature dependence of saturation flux density $B_S(T)$

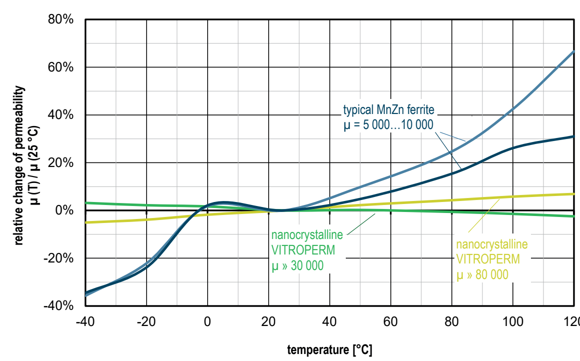

Fig. 10: Relative change of μ(T) at f = 100 kHz, normalized for room temperature

Insertion loss (and impedance) of a CMC made of VITROPERM 500 F is almost temperature-independent in the temperature range of -40 °C to above 150 °C (fig. 11a).

In contrast, ferrite chokes feature a significant drop of insertion loss with increasing temperature (fig. 11b).

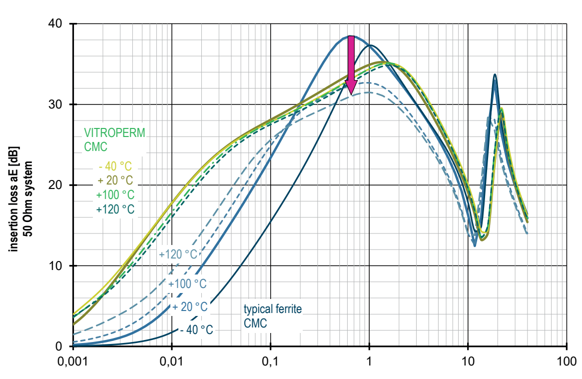

Fig. 11a: Comparison of temperature dependence of insertion loss of a VITROPERM CMC and a choke with standard MnZn ferrite core

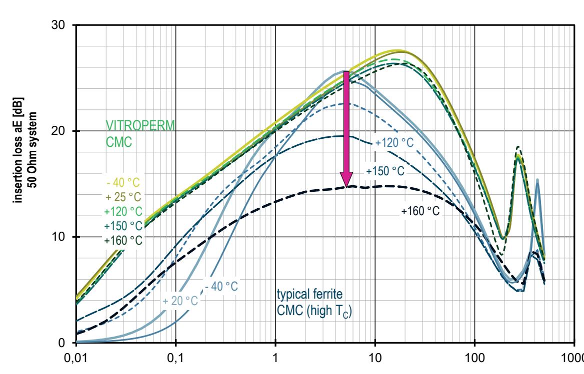

Fig. 11b: Comparison of temperature dependence of insertion loss up to 160 °C of a VITROPERM CMC and a MnZn choke using a high Curie temperature ferrite material

1) Maximum continuous temperature depends on the casing / coating materials used. Please contact VAC for more detailed information.

SATURATION BEHAVIOUR

High permeability nanocrystalline cores enable very high inductance levels in extremely compact core or choke dimensions. However, as a consequence, an increased sensitivity to asymmetric magnetization conditions caused by common mode, unbalanced or leakage currents has to be considered. These currents may occur as low-frequency leakage currents (50/60 Hz) or as medium or high-frequency interference currents. These are caused for example by long motor cables with different capacitance of the individual conductors to earth, or by resonances which occur (commonly due to bearing currents) in such cables leading to short, extremely high and rapidly declining current peaks with amplitudes of up to several 10 A_{peak} and pulse widths in the nanosecond range (1 … several 100 ns). If these common mode currents exceed the saturation level of the choke or core, the attenuation of the choke breaks down and the choke becomes less effective.

The saturation behaviour of ferrites is less sensitive due to its lower permeability. For applications with higher imbalance currents, the advantages of VITROPERM with 1.2 T saturation flux density (approximately 3 times higher than ferrites) can still be realised since VITROPERM is available in a range of permeability levels between 4,000 and 150,000. In these cases, a lower µ level may have to be selected in order to find the optimum saturation-resistant solution. Fig. 12a shows a comparison of saturation currents for different VITROPERM designs with a typical ferrite core of similar dimensions. It can be seen that the saturation behaviour of the MnZn ferrite (µ=6,000) is comparable with that of VITROPERM 500 F (µ=17,000) up to frequencies of approximately 50 kHz. At higher frequencies, however, the VITROPERM design is becoming more advantageous. The VITROPERM solution offers a 50 % higher A_L value at 100 kHz and a significantly higher impedance (note that the impedance of

VITROPERM is determined to a small part by inductance L in this frequency range). High permeability VITROPERM 500 F cores are characterized by an extremely high attenuation or impedance at low frequencies, and they are clearly superior against ferrites at high frequencies. However, the price of this superior performance is a more sensitive saturation behaviour, which is improving with increasing frequency but still more critical than that of other core materials. It should be noted that fig. 12a shows the saturation currents of the cores without winding. Depending on the number of turns, the I_{cm} values of the chokes are some 10 mA to several 100 mA, only (see tables of standard series).

Fig. 12b shows permeability characteristics under DC bias field for a VITROPERM 500 F core (μ=20,000) and 2 typical MnZn ferrites (μ=5,000 and μ=8,000, respectively). The diagram shows the significantly higher permeability and a square $\mu(H_{DC})$ characteristic of the nanocrystalline material in comparison to the rounded properties of the two ferrite cores. This behaviour complies to the linear magnetization curve of VITROPERM (figs. 8a / 8b) and leads to nearly constant inductance over a wide range of the DC bias fields.

VITROPERM 250 F is always used where highly saturation-resistant solutions are required for applications with very high common mode or unbalanced currents. However, it cannot equal the high attenuation of VITROPERM 500 F.

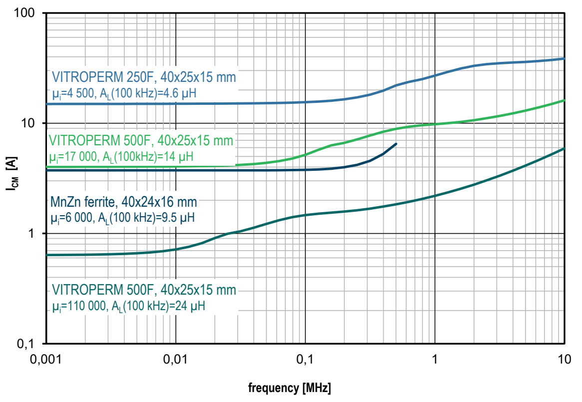

Fig. 12a: Comparison of saturation behaviour of VITROPERM 500 F, VITROPERM 250 F and MnZn ferrite

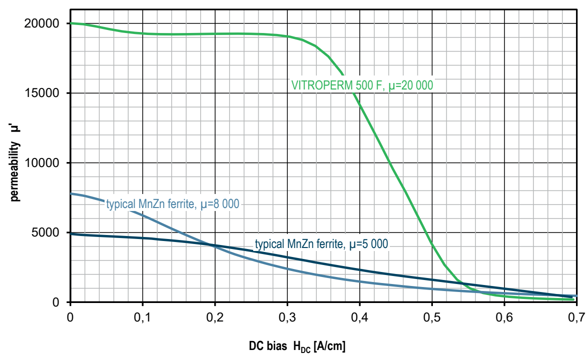

Fig. 12b: Comparison of permeability characteristics under DC bias field for VITROPERM 500 F and two typical MnZn ferrites

DESIGN ADVANTAGES WITH VITROPERM

The superior material properties of nanocrystalline VITROPERM enable common mode chokes with high inductance/ impedance with a small number of turns, resulting in reduced copper losses, low winding capacitance and excellent HF performance.

Due to the high initial permeability, low winding capacitance and a low Q-factor (above 100 kHz) VITROPERM CMCs offer a broadband insertion loss curve ranging from 10 kHz up to several MHz and improved attenuation behaviour at both low and high frequencies, in comparison to conventional ferrite chokes with similar core dimensions and identical windings (see fig. 13).

Better attenuation properties and an extended operating temperature range allow a reduction of the component volume by a factor of up to 3 or more under similar conditions. Note that the insertion loss curve of the small VITROPERM choke in fig. 14 is similar to that of ferrite materials at frequencies of about 600 kHz - 1 MHz and is superior below 500 kHz and above 1 MHz.

The excellent attenuation of VITROPERM CMCs simplifies the filter design in a wide frequency range.

For laboratory tests, VAC offers different sample kits with selected standard cores and chokes.

STANDARD SERIES OF VITROPERM CORES

Our VITROPERM cores are available with different A_L-levels for many core sizes. Thus, saturation-resistant solutions are available for various fields of applications. Common mode currents may occur as interference currents, bias currents or, primarily, unbalanced currents. If the common mode currents exceed the saturation currents (I_{cm}) of the cores or chokes, cores with higher saturation resistance must be used. High A_L values (high μ) are more suitable for typical single-phase applications with low unbalanced current (e.g. switched-mode power supplies), while cores with lower A_L values are often used in 3-phase applications with high unbalanced currents (e.g. frequency converters with long motor cables).

NANOCRYSTALLINE VITROPERM CORES WITH EPOXY RESIN COATING

Although the epoxy resin coating is suitable for direct winding, we recommend additional insulation between core and winding for enhanced insulation requirements. The epoxy resin is suitable for continuous operational temperatures of up to 120 °C (UL compliant 105 °C) and complies with the **UL94-V0 standard (UL File Number: E214934), class A (105 °C).**

NANOCRYSTALLINE VITROPERM 500 F, VITROPERM 712 F AND VITROPERM 250 F CORES IN PLASTIC CASING

The plastic cases are suitable for direct winding and offer good mechanical protection of the nanocrystalline core material. This enables the best magnetic properties and highest permeability levels to be maintained. Additional winding protection is optional for heavy wire windings, where there may be a danger of core damage. The plastic materials comply with the standards **UL94-V0 / HB for small cores (UL File Number: E41871), class B (130 °C) and UL94-V0 (UL File Number E41938), Class F (155 °C).**

* A_L = inductance for N = 1 (tolerance +45 % / -25 %)

** I_{cm}: the listed saturation currents are guidelines only. They are calculated for nominal core dimensions at room temperature and for approx. 70 % saturation flux density. The frequency-dependent saturation behaviour is demonstrated in fig. 12.

STANDARD SERIES VITROPERM 550 HF CORES

Tape wound cores made of our new VITROPERM 550 HF offer improved attenuation at high frequencies (f > 100 kHz) without loss of saturation behavior in comparison to our standard VITROPERM 500 F cores and typical EMI ferrites. These cores enable high noise suppression in innovative filter designs with smaller volume and/or higher performance.

Figure 15 shows the relative permeability between VITROPERM 550 HF and VITROPERM 500 F for cores of the size of 26 x 16 x 10 mm. The improved behavior is most dominant at about 100 kHz with more than 35 % higher permeability compared to VITROPERM 500 F. The higher permeability at high frequencies translates into a higher impedance of the choke (figure 16) and thus higher insertion losses (figure 17) for mitigating EMI.

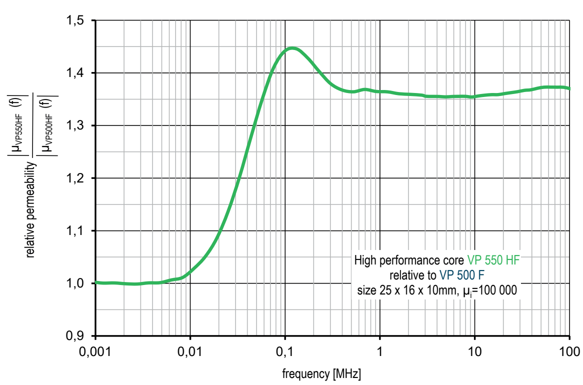

Fig. 15: Relative permeability between VITROPERM 550 HF and VITROPERM 500 F for cores of the size of 26 x 16 x 10 mm.

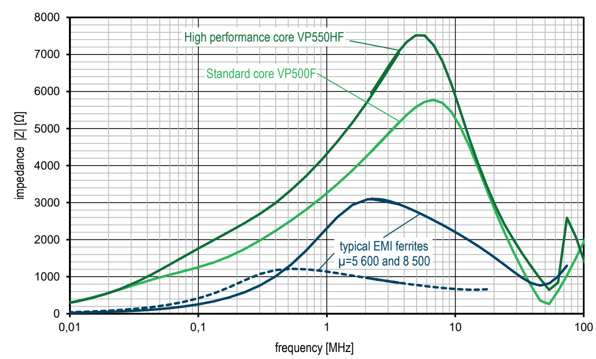

Fig. 16: Comparison of the impedance IZI (f) of VITROPERM 550 HF vs. VITROPERM 500 F and typical ferrites. In each case, the core size is 25 x 20 x 10 mm, wound with 14 turns.

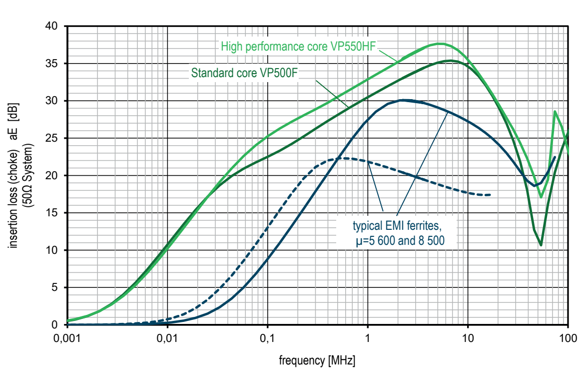

Fig. 17: Comparison of the insertion loss aE of VITROPERM 550 HF vs. VITROPERM 500 F and typical ferrites. In each case, the core size is 25 x 20 x 10 mm, wound with 14 turns.

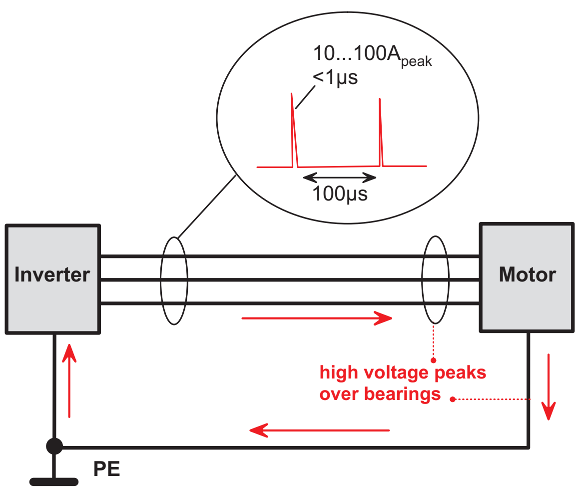
CORE STACK ASSEMBLIES WITH NANOCRYSTALLINE CORES

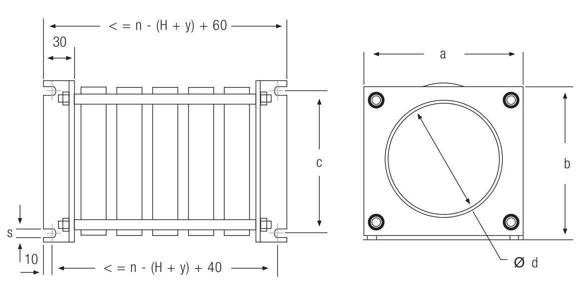
Single-turn chokes employing a number of nanocrystalline cores assembled in a stack are an effective solution for bearing current problems or extremely high common mode noise from other causes in large-scale variable speed drives, wind generators and other applications.

In these applications resonance phenomena cause high-amplitude interference currents with peak values ranging from several 10 A to over 100 A. These generally take the form of short and thus high-frequency current peaks. For these applications, VAC offers assembled core stacks which can be easily and securely integrated into existing applications with the minimum of effort.

The core stacks are available in two sizes with two different through-hole diameters. They are custom-designed, allowing an individual selection of core type and the number of stacked cores (up to 7 pieces) depending on the required saturation level and the required inductance.

More detailed technical information and the data sheets are available at www.vacuumschmelze.com.
Please scan the QR-code belonging to this chapter which will lead you automatically to the respective site.





Dimensions of the core stack assemblies

	a	b	c	d	s
	(mm)	(mm)	(mm)	(mm)	(mm)
Size 1	120	130	70	~70	7
Size 2	180	190	130	>118	10

n = number of stacked cores
H = maximum core height
y = 9.5 for epoxy coated cores, T60004…
y = 10.2 for cased cores, T60006…
L = n*(H+y)+60
The inductance L of a core stack can be calculated by multiplying the number of stacked cores with the A_L-value of the single core.
A_L: inductance of single core
I_{cm}: maximum permissible leakage or common mode current
Calculated guideline for nominal core dimensions at room temperature and for approximately 70 % saturation flux density.

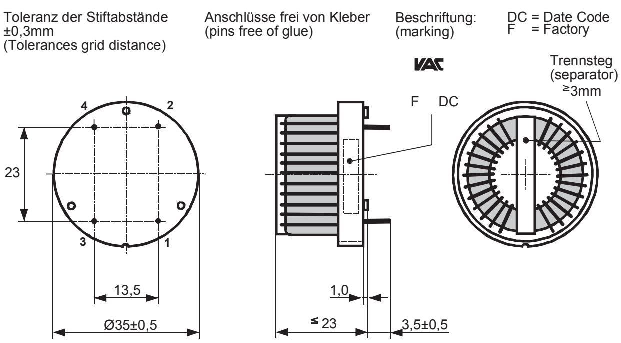
COMMON MODE CHOKES
UL1446 STANDARD SERIES

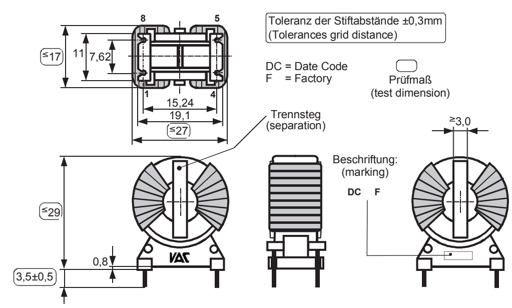
Common Mode Chokes using VITROPERM cores offer universal solutions for various EMI problems due to highest inductance at a low number of turns in compact designs, excellent high frequency properties and stable performance over a wide temperature range.

All standard types in low profile or upright constructions are designed for operation in grid connected RFI filters or for applications with higher operating voltages. Construction, production and testing of the chokes are in accordance with **EN50178, resp. IEC 62109**. The plastic materials comply with the following UL standards **UL94-V0/HB for small chokes (file number E41871) and UL1446 (file number OBJY2.E329745) for temperature class B (130 °C)**.

Example: low profile



upright profile



GENERAL INFORMATION

I_N = nominal current in each winding

$U_{N\ OVCat\ III\ /\ II}$ = operating voltage for overvoltage category III/II

L_N = nominal inductance, tolerance +50 % / -30 %

Ambient temperature T_a = -40 °C ... +70 °C (short-term +90 °C)

Operating temperature T_{op} = -40 °C ... +130 °C (short-term +150 °C)

R_{Cu}: winding resistance per winding

IZI: choke impedance

f_R: choke resonance frequency

The standard chokes are designed for a temperature rise of ΔT = 45…60 K at T_a = 70 °C and $I = I_N$ in each winding. Data derating is necessary for deviating ambient temperature or deviating nominal current. Please contact VAC for further detailed information.

More detailed technical information and the data sheets are available at www.vacuumschmelze.com.

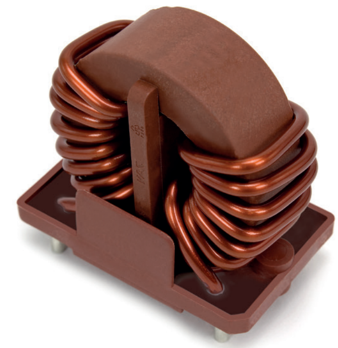
1-PHASE CMCs



For comfortable CMC selections please download our software tool (requires Microsoft EXCEL): **VAC CMC Quick-Selector**. If suitable standard CMCs are not available in the table below, please contact us using our **design check list (printed on page 26/27, QR-Code: page 24)**. For testing purposes, VAC offers special sample kits consisting of standard CMCs **CMC Sample Kit (QR-Code page 24)**.

4-FOLD CMCs

More detailed technical information and the data sheets are available at www.vacuumschmelze.com.
Please scan the QR-code belonging to this chapter which will lead you automatically to the respective site.

STANDARD SERIES 4-FOLD CHOKES

Part number T60405-	I_N A	Design	U_N OVCat III/II V	L_N 10 kHz mH	L_N 100 kHz mH	R_{Cu} typ. mΩ	|Z| 100 kHz Ω	f_R typ. MHz	I_{cm} 10 kHz mA	Dimensions l mm	Dimensions w mm	Dimensions h mm
S6123-X400	10** 12*	low profile	600/1000	4x6.9	4x1.6	7.66	1500	1.4	40	51	51	33
S6123-X401	16** 20*	low profile	600/1000	4x3.6	4x0.8	2.75	860	3.4	90	51.5	51.5	33
S6123-X402	24** 30*	low profile	600/1000	4x3.2	4x0.7	1.5	750	3.5	100	60	60	33.5
S6123-X403	32** 40*	low profile	600/1000	4x1.4	4x0.3	0.82	360	7	160	60	60	33

* for $T_a \leq 60\,°C$ ** for $T_a \leq 85\,°C$

CMCs FOR HIGH POWER CENTRAL AND UTILITY GRADE PHOTOVOLTAIC-INVERTERS UP TO THE MW-RANGE

[1] Design example: $I_{rms} = 2 \times 400$ A, $L = 2 \times 1.5$ mH, $U_{is} = 1000\ V_{rms}$,
mechanical dimension 276 mm x 287 mm
(without cable and cable lugs)

FURTHER DESIGN SUPPORT

For CMC selections (even at deviating operational data) please download our software tool (requires Microsoft EXCEL) VAC CMC Quick Selector which can be accessed using the QR-codes in this brochure that link to the product pages.

If you cannot find a suitable CMC from the listed standard range, please contact us using our design checklist.

Checklist EN 50178

Checklist IEC 62109 & IEC 61800

For testing purposes, VAC offers special sample kits consisting of tape-wound cores Core Sample Kit VITROPERM and Common Mode Chokes CMC Sample Kit.
